AMENDMENTS TO THE SPECIFICATION

Please amend the specification as indicated hereafter. It is believed that the following amendments and additions add no new matter to the present application.

In the Specification:

Please amend the paragraph starting on p. 5, line 3 as follows:

The transfer device can be designed for single-pass or multiple-pass flow paths. A single-pass device accepts a flow from one side of the unit, and exhausts that flow on the [[5]] other side of the unit, wherein the flow makes a single-pass through the exchange media. A multiple-pass device, for example a double-pass device, enables the flow to traverse the wheel twice before being exhausted. In this double-pass embodiment, the length of the wheel can be half that used in relation to the length of the wheel in the single-pass device, but the wheel would be larger in diameter than the single-pass wheel. In an alternative embodiment of [[10]] the double-pass device, the flow may traverse the length of the housing assembly twice, but only encounter media in one trip (length) through the device. In this alternative double-pass embodiment, the length of the wheel can be equal to that used in relation to the length of the wheel in the single-pass device, but the wheel would be smaller in diameter than the double-pass wheel that has media in both passes.

Please amend the paragraph starting on p. 6, line 20 as follows:

Fig. 4 is a cross-sectional perspective view of an exemplary exchange media. [[.]]

Please amend the paragraph starting on p. 8, line 23 as follows:

Beyond fuel cell systems, other environments for the present species transfer device [[an]] can include HVAC systems wherein the device is a heat exchanger, or a chemical process where various gases and liquids may be removed, concentrated or transformed.

Please amend the paragraph starting on p. 11, line 1 as follows:

$^{\circ}\text{C}$ to about $10 \times 10^{-7}/^{\circ}\text{C}$, most preferred from about $3 \times 10^{-7}/^{\circ}\text{C}$ to about $8 \times 10^{-7}/^{\circ}\text{C}$, optionally having an added sorbent, preferably a desiccant. Exemplary substances having low CTEs include cordierite and cordierite containing substances. In one embodiment of the present invention, the heat wheel is formulated to have a CTE low enough to prevent or reduce the wheel from changing shape, preferably by less than about 0.001 inches in any direction in response to changes in temperature such that the inlet and exhaust streams do not commingle. The species transfer device having such ~~[[an]]~~ a heat wheel optionally includes a sealing system.

Please amend the paragraph starting on p. 11, line 9 as follows:

Cordierite is a crystalline magnesium aluminum silicate having an average linear coefficient of thermal expansion reported to be in the range of 12 to $16 \times 10^{-7}/^{\circ}\text{C}$. It has relatively high refractoriness and a melting point of about 1460°C . Cordierite has been used in cookware, dinnerware, and in catalytic converters of automobiles. U.S. Pat. No. 4,298,059 discloses the use of cordierite in a recuperative heat exchanger. U.S. Pat. No. 4,967,726 discloses a heat wheel made of cordierite used in ~~[[a]]~~ heating and ventilation systems for buildings. U.S. Pat. No. 6,183,895 discloses the use of cordierite as a carrier for a metal in a reforming catalyst used in a fuel cell power generating system. U.S. Pat. No. 5,702,508 discloses the use of cordierite as a ceramic rotor used to dry gases.

Please amend the paragraphs starting on p. 12, line 9 as follows:

Sealing system 45 of Fig. 3 provides a diametrical seal between the two flow paths 20 and 30. Sealing system 45 can comprise a contact seal 108. Contact seal 108 can be made of low friction material. Suitable low friction materials include but are not limited to TeflonTM or PeekTM. In one embodiment, seal 108 is in direct contact with the end of media 80 and is maintained there by constant pressure exerted by an arrangement of springs 109 acting between the housing end ~~43~~ and 43 and the seal plate 108. The variable space between the seal plate 108 and the housing end ~~43~~ can be sealed, preferably by a congruent gasket, more preferably by a silicon gasket, that allows axial movement of the seal plate 108 while preventing flow between the seal plate 108 and the end of the housing 43. This slight axial movement allows for thermal expansion of the assembly and for wear of the sealing surfaces.

In other embodiments, the exchange media 80 comprises channels connecting first and second axial faces, a core, and a rim. Alternatively, the media wheel 80 may be a solid cylinder of media, without a core. The wheel 80 includes a plurality of parallel channels, which can generally be in the form of a hexagon in cross section, among other geometries. In one preferred embodiment, the channels are rectangular, more preferably square. The walls of the channels have a minimum thickness to inhibit the effect of the wall thickness increasing the pressure drop through the wheel 80 and yet provide the wheel 80 with sufficient structural integrity to be self supporting. The channels can be sized such that a distance between and along longitudinal axes of adjacent channels is generally uniform. Thus, the channels of the media 80, due to their hexagonal cross-sectional configuration, are closely adjoined to increase the available transfer surface per unit of volume. The use of channels having a cross section that is generally in the form of a hexagon is advantageous over other geometries, such as sinusoidal, square, and triangular as the hexagon shape provides a greater available transfer surface area (i.e., based upon standard measurements and calculations of the geometries after

Please amend the paragraph starting on p. 13, line 6 as follows:

Generally, the larger the surface area of the exchange media, the more efficient the exchange media. Suitable surface areas of an exchange media are about 2000 – 5000 meters²/meters³ with appropriately sized channels. It will be appreciated that the exchange media can have more or less surface area depending on the desired efficiency of the ~~media~~ media. Although in a preferred embodiment, the hexagonal flow channels extend axially through the entire length of the wheel 80, in the direction of first and second stream flow, the size and orientation of the channels can vary according to need, but must be sufficiently small to maximize the total surface area for species transfer, yet sufficiently large relative to their length to minimize resistance to the stream flow.

Please amend the paragraph starting on p. 14, line 2 as follows:

In still ~~other~~ another embodiment, the exchange media 80 can be optionally coated with a sorbent, which according to a heat wheel embodiment, can be a water selective molecular sieve or desiccant. Exemplary desiccants include but are not limited to silica gel, activated alumina,

Serial No.: 09/975,870

Page 5

gamma alumina, titanium silicate, glycols, calcium chloride, lithium chloride or other hydrophilic materials. In one embodiment, the desiccant-coated exchange media provides surface area for moisture transfer. A sorbent is herein defined as a substance that has the ability to take up and hold species, as by absorption or adsorption. The sorbent is chosen for its particular characteristics vis-à-vis the species to be transferred. If the species transfer device is used to transfer latent heat between streams, the sorbent can be a desiccant. If the species is CO, then the sorbent is a substance that can collect and release CO between the streams.

Please amend the paragraph starting on p. 14, line 20 as follows:

The suitable sorbents can include zeolites. Zeolites are highly crystalline aluminosilicate frameworks comprising $[\text{SiO}_4]^{4-}$ and $[\text{AlO}_4]^{5-}$ tetrahedral units. T atoms (Si, Al) are joined by $[[\text{an}]]$ oxygen bridges. Introduction of an overall negative surface charge requires counter ions e.g. Na^+ , K^+ and Ca^{2+} . The zeolite crystals contain water, and as the water is driven off by heating, there is no discernible collapse of the framework structure. This leads to a highly crystalline, microporous adsorbent that has an internal structure which can be easily tailored to adsorb any number of species.

Please amend the paragraph starting on p. 14, line 27 as follows:

Zeolites have beneficial molecular sieving properties. The pore size distribution can be modified, enabling the zeolite to be used as a so-called molecular sieve. Molecules which are too large to diffuse into the pores are excluded, whereas molecules which have a kinetic diameter smaller than the pore size, diffuse into the pores, adsorb and under certain conditions are capable of undergoing catalytic reactions. An example of this is in the sieving of straight and branched ~~ehained~~ chain hydrocarbons to increase the octane number of gasoline.

Please amend the paragraph starting on p. 16, line 2 as follows:

A labyrinth seal can alternatively be used with a heat wheel 80 as shown in Fig. 6 wherein a rotary valve 162 is in radial form. The radial seal 164 divides the heat wheel 80 into two sides, with wedges 166 on the left separated from the wedges 168 on the right. The spokes 172 hold pressure, and wiping seals 174 keep the streams from intermixing. In this embodiment of the

Page 6

species transfer device 10, the inlets 24, 34 of the housing enclosure 42 direct the first and second entering streams 20, 30 into the rotary valve 162. By rotating the housing 40, the first and second streams flow axially through the alternating media wedges 166 and 168. [.]

Please amend the paragraph starting on p. 20, line 17 as follows:

The optional desiccant of the sensible and latent heat transfer device is capable of removing moisture from the cathode reactant exhaust stream, which removal releases heat and raises the exhaust stream temperature, which in turn heats the media of the enthalpy wheel. This same heat is used to power the release phase in the cathode reactant inlet stream upon rotation of the enthalpy wheel. A desiccant material naturally interacts with moisture from gases and liquids. The material becomes saturated as moisture [is] interacts with the desiccant; but when exposed to a dryer stream, the desiccant releases moisture - or regenerates - and can be used again. The enthalpy wheel of the present invention can include solid desiccants, for example, silica gel, activated alumina, gamma alumina, lithium chloride salt, and molecular sieves. Titanium silicate, a class of material called 1m, and synthetic polymers are newer solid desiccant materials designed to be more effective for cooling applications. Alternatively, the enthalpy wheel can include liquid desiccants, for example, lithium chloride, lithium bromide, calcium chloride, and triethylene glycol solutions.
